Title: Heat Transfer in Tubes with Packing

Original Periodical: Zh. tekhn. fiziki, 1956, 26, No 4, 800-808

Abstract: An experimental investigation was made of the heat transfer from air to the walls of a tube, filled with granular packing. The charge used was lead shot 2 mm in diameter, quartz sand with an average particle diameter of 1 and 3 mm, and steel balls 6 mm in diameter. Experiments with sand were carried out for a range of Reynolds numbers from 0 to 245; the obtained values of the heat transfer coefficient ranged from 16.2 to 48 kcal/m^2hr deg. In experiments with steel balls, the range of Reynolds numbers was extended to Re = 632; α = 25.6 - 90 kcal/m^2hr deg. The experiment carried out with shot gave approximately the same results as for steel balls. In experiments with increasing values of Reynolds numbers, only a slow gradual increase in α with stream speed, was observed and not a direct proportionality to the latter. In the laminar region, the coefficient of heat transfer

CARD 1 / 2 PA - 1257

SUBJECT USSR / PHYSICS
AUTHOR VETROV, B.N., TODES, O.M.
TITLE The Heat Transfer in Tubes with Depositions.
PERIODICAL Žurn. techn. fis, 26, fasc. 4, 800-808 (1956)
Publ. 4 / 1956 reviewed 9 / 1956

Theoretical analysis of the problem: The present work theoretically and experimentally investigates the heat transfer from a moved gas and from an immovable layer of solid particles to the walls of a tube. The velocity of the steady heat exchange through the wall of the tube is essentially determined by the effective heat conductivity λ_e of the layer. In the case of d/D > 1/12 the dependence of the NUSSELT number on an additional criterion for d/D must be considered. If the material of the deposited particles is not too much heat conductive, another criterion for λ_g / λ_s must yet be considered. Here d denotes the diamter of the deposited particles, D - diameter of the tube, λ_g and λ_s heat conductivity of the gas and of the solid particles respectively. In the case of a flowing gas REYNOLD'S and PRANDTL'S numbers must in addition be taken into account.
Experimental methods are discussed on the basis of a drawing showing the test order which, essentially, consists of a brass cylinder enclosed by an exterior shell through which water from the main flows. The height of the deposited layer can be regulated by means of a grid. Several thermopiles introduced into the cylinder through transversal channels leading through the shell

measure the difference in temperatures in the interior of the cylinder and in the surrounding medium.

Experimental results: A certain concrete experiment finished the following data: Air consumption - 91 litres per minute, = 5,45 m^3/hour. The flow velocity computed herefrom amounts to 1090 m/hour. The temperatures indicated by the thermopiles after temperature distribution has become steady are shown in a table. The coefficient of heat transfer from the cylindrical layer to the walls is then 25,7 KKal/m^2.hour.grad, and REYNOLD'S number on the occasion of this experiment amounts to 52,5. The results of all experiments which were carried out with sand are shown together in a table. At Re < 50 the values of the heat transfer coefficient fluctuate about 20 KKal/m^2.hour.grad. A special test carried out at Re = 0 by the method of quasistationary cooling of the entire tube furnishes the value 16,2 KKal/m^2.hour.grad for these coefficients. At Re → this coefficient probably tends towards the value 16, which agrees well with the data of other tests. Tests carried out in a similar manner with steel balls of 6 mm diameter (porosity ε = 0,40) furnish a value of ~ 22 for the heat transfer coefficient at Re → 0. Similar results were obtained also with shot with d = 2 mm.

1968. Vetrov, B. N., and Todes, O. M., Propagation of heat waves due to the heating-up of furnace charges by a gas flow, III, (in Russian), *Zh. tekh. Fiz.* 25, 7, 1242–1247, July 1955.

This is the third and the final paper by the same authors on the subject of finding the coefficient of heat transfer from a hot gas flowing through a granulated material along a cylindrical vessel. The three papers appeared in the same issue of title source, 25, 7, July 1955, and are being reviewed currently. In the first paper under the title: "Measuring the coefficient of heat transfer from a flowing gas to a furnace charge," authors assumed only forced convection and neglected heat transfer by conduction. In the second paper under the title: "Heating granulated material by conduction along a cylindrical vessel at nonadiabatic conditions," authors describe an investigation of heat transfer along the same charge by conduction only. In this report, authors present the mathematical solution of the heat equation with boundary conditions existing in their experimental set-up, in which they take into account both forced convection and conductivity along the vessel. The solution giving the temperature as a function of time and distance from the front of the charge provides a formula for finding the convection heat transfer from the gas and the conductivity of the charge. As the conductivity at small velocities (small Reynolds numbers) cannot be neglected, authors propose a modified Nusselt number which would take this into account for small values of Reynolds number (in the relation Nusselt number-Reynolds number for forced convection). This would enable people in industry to evaluate directly the width of the heat wave in which they are mainly interested, without bothering about convection and conduction.

1967. Vetrov, B. N. and Todes, O. M., Heating granulated material by conduction along a cylindrical vessel at non-adiabatic conditions. II. (in Russian) *Zh. tekh. Fiz.* 25, 7, 1232-1241, July 1955.

This paper is the second one on the same subject published in the same issue of title source, 25, 7, July 1955. In the first paper, under the title "Measuring the coefficient of heat transfer from a flowing gas to a furnace charge," authors report on their investigations of heating a charge of granulated material in a cylindrical vessel by blowing hot air through it. The measurements gave a temperature-time curve from which authors evaluated heat transfer and other thermal coefficients of the charge, assuming heat-transfer by forced convection only and neglecting heat conduction. At large gas velocities, the thermal coefficients found experimentally gave good agreement with the established Nusselt number-Reynolds number relation for the forced convection. At small velocities, discrepancies appeared, due to conduction heat transfer along the charge itself, which was negligible at large velocities as compared with the forced convection heat transfer from the gas to the charge, but not so at small gas velocities.

In this paper, authors present results of heating a charge of granulated material by conduction only along the same cylindrical vessel. Theoretical solution was obtained in two stages. The first approximation was obtained by assuming that the charge is a solid cylinder (instead of porous granulated mass), and the boundary-value problem for the actual case was solved with the help of this first approximation. The experiments consisted of heating only the front of the charge and letting the heat be transferred by conduction along the charge (not letting the hot air through it), and plotting temperature-time curves. The experimental results agree with the theoretical solutions and authors are able to introduce a correction in their original results to make them agree with Nusselt number-Reynolds number relation.

Title : Measurement of heat emission coefficient from a gas flow to the furnace charge in conditions of non adiabatic heating. I.

Periodical : Zhur. Tekh. Fiz., 25, No 7, 1217-1231, 1955

Abstract : An indirect method is applied for determining the coefficient of heat emission by a hot gas stream to the furnace charge by comparing experimental with theoretical curves. The theoretical results were improved by deriving a formula for computing the volume coefficient of heat emission in real, i.e. non adiabatic conditions. These theoretical results agree with experimental data. Ten references, including 5 foreign.

Title : Conductive heat transfer along granulated material in a pipe in non adiabatic conditions. II.

Periodical : Zhur. Tekh. Fiz, 25, No 7, 1232-1241, 1955

Abstract : A heat wave was theoretically deduced originating in heating of one end of pipe filled with granulated material and cooled on its lateral surface. The height of this wave decreases exponentially while the wave front moves with constant speed. Tests carried out on several pipes filled with steel balls or quartz sand confirmed the theoretical anticipations. Two references.

ABSTRACT: Nikolay Afanas'yevich Tishchenko completed the Khar'kov Electrotechnical Institute in 1930, after working as an electrician in a metallurgical plant from 1923-1926. He was active in the development of domestically produced electrical equipment for rolling mills and metallurgical furnace works. He was active during WWII in restoring electrical equipment damaged by the Germans. After the war, he was active in developing electrical drive equipment for both domestic and foreign metallurgical plants. He has been active in scientific work, publishing over 45 works in such varied fields as electric drives, equipment reliability and productivity of labor. Orig. art. has: 1 figure. [JPRS]

TITLE: The Practice of Remote Air Supply of an Oxygen Plant by Means of a Pipeline (Praktika zabora vozdukha kislorodnym tsekhom po truboprovodu na dal'nem rasstoyanii).

PERIODICAL: Kislorod, 1957, Nr 5, pp. 24-25 (USSR)

ABSTRACT: In the factory area of the Plant for Synthetic Caoutchouc in Karaganda there are beside the technological halls two more great carbide halls as well as halls for the production of great quantities of acetylene, which serve also for its hydration to acetyldehyde. During production in these halls it is unavoidable that acetylene is constantly effused into the air. The air fractionating blocks are equipped with acetylene adsorbers. These could, however, not save the plants from an explosion in 1953. Of late, after the installation of the new pipeline, the adsorbers are not longer switched on. The remote air-supply, as a protection against air impurities, was introduced in 1949. From the working practice of the oxygen plant it was seen that the remote air-supply sufficiently protects the air fractionating apparatus against acetylene accumulation. The cases where the acetylene analysis was positive became more rare. The analyses were made three times a day by means

Card 1/2

of the condensation-calorimetric method. In connection with the air-supply from the area of the oxygen plant the authors also investigated the wind directions and their influence on the accumulation of acetylene in the apparatus in the course of 13 days. On this occasion it turned out that the wind direction as well as the distance between the air fractionating hall and the source of impurity influence the accumulation of acetylene in the apparatus. When the pipeline for the air-supply is sufficiently distant from the production site of acetylene it can not completely avoid the entrance and the accumulation of acetylene but it can decrease its content in the apparatus. There is 1 table.

TITLE: What Prevents Economizing Fuel (Chto meshayet ekonomit' aviatoplivo)

PERIODICAL: Grazhdanskaya aviatsiya, 1957, Nr 12, p 28 (USSR)

ABSTRACT: The author first refers to an unidentified operational unit, where fuel economy was achieved by means of proper adjustment of the fuel-injection assembly of the ASh-82FN engine, an exact computation of flights to comply with the schedule, the use of "cruising graphs", and optimum speeds of 45 to 60 per cent of the maximum output of the power plant. Criticism is directed against the Fuel Consumption Norms issued in February 1952, which are based on the actual flight time. The author demands that the distance covered will be made the basis of fuel allowances. Along with the plane crews, the maintenance workshops and the traffic control agencies are held responsible for fuel economy.

TITLE: The PMC-2 (RMS-2) Mass Spectrometer Designed for Studying Chemical Reactions and the Determination of Free Radicals

PERIODICAL: Pribory i tekhnika eksperimenta, 1960, No.6, pp.78-84

TEXT: A double magnetic mass-spectrometer designed for studying reactions in the gaseous phase and, in particular, for the determination of free radicals is described. Two methods are used to produce the ions. In the first method the mixture to be analysed is ionized by charge transfer to specially produced ions. The latter are formed in a separate ion gun by means of electron bombardment and are mass-analysed in a small magnetic analyser. In the second method the mixture under consideration is ionized directly by electron bombardment. Quasi-monochromatization is achieved by a method based on that reported by Fox et al. (Ref.11). The gas from the "reactor" is introduced into the ion source in the

Card 1/6

form of a molecular beam which is mechanically interrupted at a known frequency. In distinction to the method described by Foner and Hudson (Ref.2), in which the molecular and ion beams are perpendicular, in the present system the two beams are coaxial, which means that smaller voltages are necessary for the "extraction" of the ions from the ionization region and it is possible to reduce the intensity of the background mass-spectrum. A particular feature of the present instrument is the use (in the measuring part of the spectrometer) of K-stabilisation of parameters such as the accelerating voltage, the voltage supplying the detector, the emission current of the ion gun cathode, and the supply voltage for the ion source cathode. This was described by the second of the present authors in Ref.10. The mass numbers are determined from a knowledge of the magnetic field which in turn is measured with the aid of a Hall probe (germanium crystal). The basic mass spectrometric arrangement employed is shown in Fig.2. Products of chemical reactions taking place in the "reactor" I enter the region II through a small aperture in the thin glass diaphragm 8

TITLE: Pulse apparatus for measuring nuclear magnetic relaxation time

SOURCE: IVUZ. Fizika, no. 1, 1964, 26-31

TOPIC TAGS: nuclear relaxation, spin lattice, magnetic field, radio frequency, pulse generation, nuclear magnetization, precession, pulse modulator, amplifier

ABSTRACT: The construction details of a pulse-measuring instrument have been described. Measurement of a wide range of nuclear relaxation times T_1 and T_2 in liquids as well as in solid bodies is possible using this apparatus. T_1 is the spin-lattice relaxation time and T_2 is the spin-spin or transverse relaxation time. For both relaxation measurements the specimen is placed in a constant magnetic field H_0 and, after attaining thermal equilibrium, is subjected to the action of radio frequency (rf) field H_1 in the form of a direct pulse. The frequency field H_1 must satisfy the resonance condition

$\omega = \gamma H_0$

Card 1/2

ACCESSION NR: AP4020295

γ-gyromagnetic ratio. Under the rf field the nuclear magnetization vector departs from its equilibrium position by the angle Θ where

$$\Theta = \gamma H_1 t_w.$$

A list of methods for measuring the relaxation time is given, consisting of measuring the decay of spin-echo amplitudes and the decay of free precession after the rf impulse. The block-diagram of an instrument for measuring the relaxation time is given. The specimen is bombarded by an rf pulse coming in from the amplifier capacity of a transmitting counter coil. The amplifier capacity is guided by a modulator which receives the pulses from a programmer. The time sequence of these pulses is determined experimentally by selecting a particular program. The instrument is also shown to be capable of measuring the self-diffusion coefficient. Orig. art. has: 4 formulas, 3 figures, and 1 table.

form of a molecular beam which is mechanically interrupted at a known frequency. In distinction to the method described by Fener and Hudson (Ref.2), in which the molecular and ion beams are perpendicular, in the present system the two beams are coaxial, which means that smaller voltages are necessary for the "extraction" of the ions from the ionisation region and it is possible to reduce the intensity of the background mass-spectrum. A particular feature of the present instrument is the use (in the measuring part of the spectrometer) of K-stabilization of parameters such as the accelerating voltage, the voltage supplying the detector, the emission current of the ion gun cathode, and the supply voltage for the ion source cathode. This was described by the second of the present authors in Ref.10. The mass numbers are determined from a knowledge of the magnetic field which in turn is measured with the aid of a Hall probe (germanium crystal). The basic mass spectrometric arrangement employed is shown in Fig.2. Products of chemical reactions taking place in the "reactor" I enter the region II through a small aperture in the thin glass diaphragm 5

Card 2/6

in the form of a molecular beam. This molecular beam is collimated further by the diaphragm 6 which separates the volume II from the region in which ionisation takes place. A moveable screen 7 is placed in front of the diaphragm 6 and interrupts the molecular beam 33 times per sec. In the case of ionisation by charge transfer, the primary ions are produced in the ion gun III. The ion beam formed there is mass analysed in the 60° magnetic analyser IV which has a working radius of 100 mm. The primary ion beam, consisting of ions of the required mass, intersects the molecular beam and charge transfer takes place. In the case of ionisation by electron impact, the source becomes analogous to that described by the first and fourth of the present authors in Ref.9. In the case of ionisation by a monochromatized electron beam, the modulation of the molecular beam by the chopper 7 is not employed. The ion current in the mass-spectrometer is measured either by a d.c. amplifier or by an electron multiplier. The vacuum chamber of the mass-spectrometer is an all-metal system and all the sections are out-gassed at 300 to 350°C before the operation is begun. As an illustration of

The PMC-2 (RMS-2) Mass Spectrometer Designed for Studying Chemical Reactions and the Determination of Free Radicals

the possible applications of the instrument, data are quoted on the formation of free radicals in the pyrolysis of hydrazine. In these experiments the hydrazine entered from a glass container into a quartz capillary through a control valve. The capillary was heated to a known temperature, as a result of which the hydrazine decomposed into nitrogen, hydrogen, ammonia and some unstable products (Fener and Hudson, Ref.18). Fig.7 shows the distribution of line intensities in the mass-spectrum of hydrazine obtained by the charge transfer method using NH_3^+ ions formed from ammonia. The pressure in the source was 5×10^{-5} mm Hg and the pressure in the chamber of the small analyser was 4×10^{-7} mm Hg. For comparison, the dotted line shows the mass-spectrum obtained on bombarding hydrazine with 50 eV electrons. Fig.8 shows the intensity distribution obtained under similar conditions at 1000°C (dotted lines) and 25°C (continuous lines). Acknowledgments are expressed to Ye. K. Bassiyan, S. T. Vorob'yev, S. G. Belov, M. N. Morozov and M. I. Markin for assistance in this work. There are 8 figures and 20 references: 11 Soviet and 9 non-Soviet.

Basic principles of alloying structural steels. S. I. Sakhin and V. Ya. Vetrov. *Stal'* 6, 538-9(1960). This investigation was concerned with methods for imparting to structural steel ductility and fibrous structure of break. These properties were induced by regulating the rate of cooling after hardening. For each kind of steel tested, at a given hardness-testing temp., shape, etc., there was a crit. rate of cooling below which brittleness appeared. The kind and quantity of alloying elements should be chosen so as to obtain as low a crit. rate of cooling as possible. M. Hosch
